## **Localization of Credential Information to Address Increasingly Inevitable Data Breaches**

Mohammad Mannan and P.C. van Oorschot

`mmannan@scs.carleton.ca`

Carleton University, Canada

## Bank customer data sold on eBay

August 27th, 2008

An investigation is under way into how a computer containing bank customers' personal data was sold on eBay.

The computer, bought by IT manager Andrew Chapman for £77, had the sensitive details on its hard drive.

**TJX breach could top 94 million accounts**  
Filings in case involving Visa cards alone as much as \$83 million

Taiwan busts hacking ring, 50 million personal records compromised

## Data Leak in Britain Affects 25 Million

IT pro admits stealing 8.4M consumer records

Hundreds of Laptops Missing at State Department, Audit Finds

“...we do not have any evidence that the data ... has been improperly accessed or misused...”

## Goals of our proposal

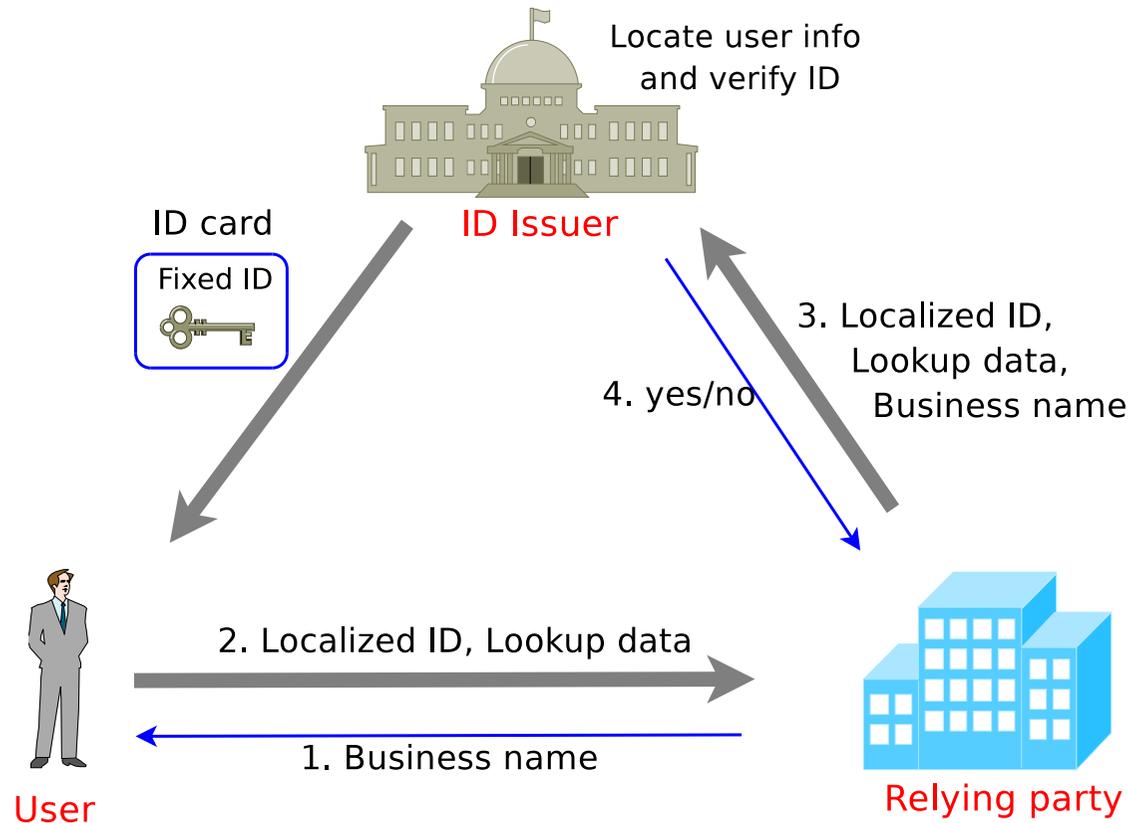

### 1. Goals:

- ▶ limit misuse of breached ID numbers from relying parties
- ▶ ameliorate huge data breaches (but not card theft or loss)
  - primary concern: identity theft

### 2. Non-goals:

- ▶ prevent data breach
- ▶ privacy

## Overview of ID localization

address "compromise once, reuse multiple times"

design for damage control

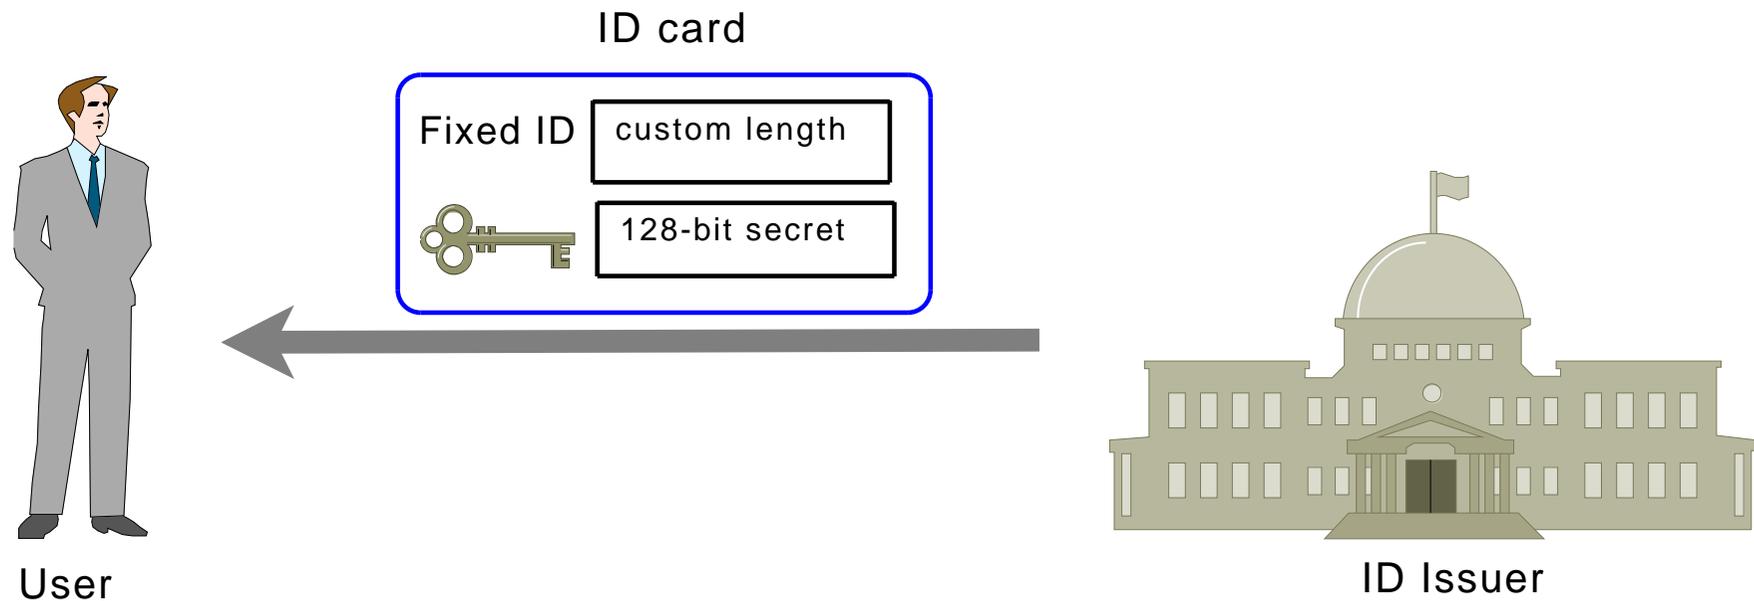

## Assumptions

1. Breaches will happen...there is no 100% prevention
2. Massive breaches usually involve relying party
3. ID issuers are targeted less often
4. Up-to-date user lookup data can be maintained
5. Online verification is possible

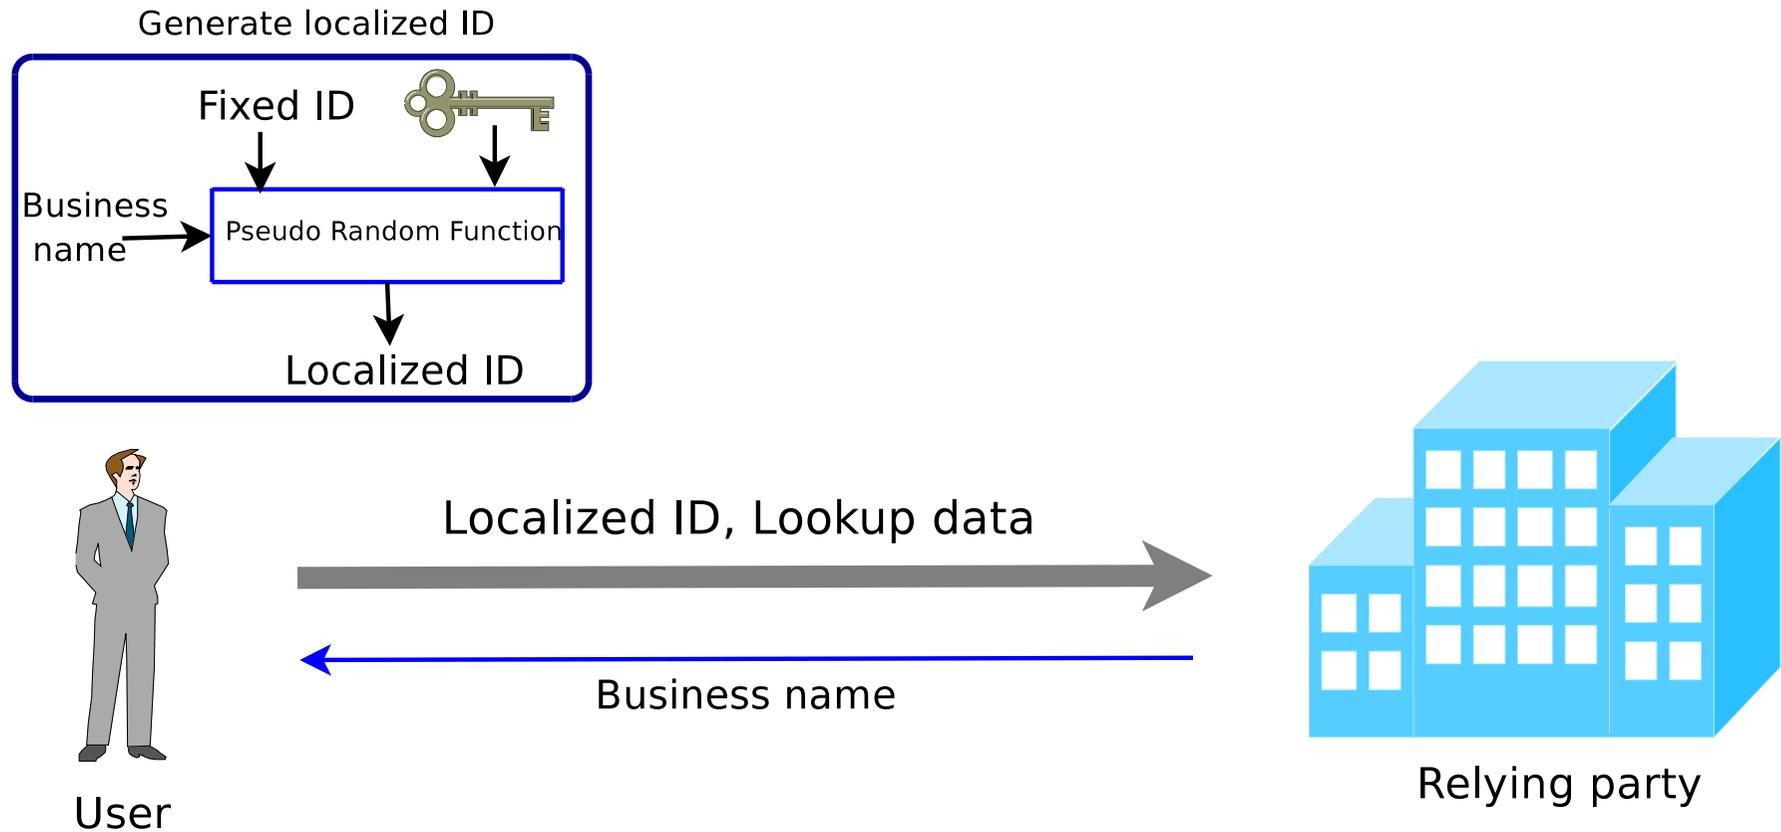

## Overview of our proposal

1. 'Localize' ID numbers so that they are valid only for a particular relying party
  - ▶ valid for Internet/phone, physical world
  - ▶ not necessarily 'one-time' use IDs
2. Limit misuse, assuming breaches can't be prevented
3. The problem domain is large: we propose several variants

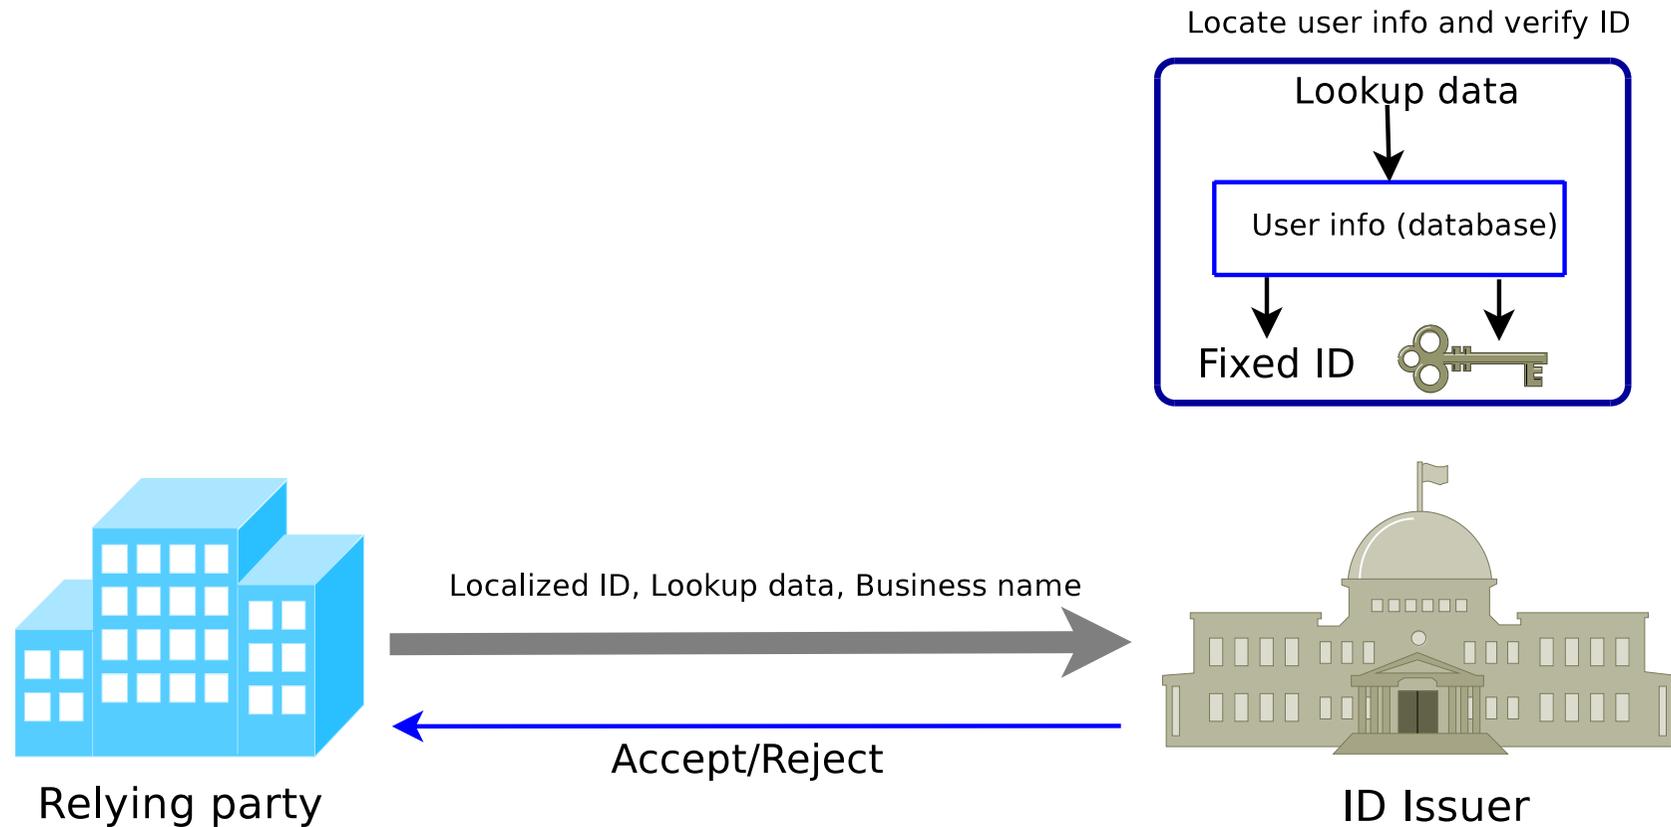

## ID localization: issue card

# ID localization: generate 'localized' ID

## ID localization: verify 'localized' ID

## Variants 1 & 2

1. Variant 1: Localized authorization code
  - ▶ PRF-output is used as authorization code (cf. CVV2)
  - ▶ fixed ID + auth. code is required for any valid use
2. Variant 2: Without chip-card or card-reader
  - ▶ shared 'secret' is printed on the card
  - ▶ localized ID (or auth. code) is generated through a personal device

## Limitations

1. Data aggregation isn't straight-forward
2. Several types of privacy-sensitive info remain unprotected
3. Requires online verification
4. Deployment would most-likely require:
  - ▶ increased liability
  - ▶ strong consumer lobbying
  - ▶ legislation/regulation

but now is the time for a change...

## Open issues

1. Using static, reusable numbers invites repeated misuse
  - ▶ but how can they be replaced?
2. Can we apply localization beyond data breaches?

Design for damage control

## Backup slides

## Current approaches that fall short

1. Data encryption
2. Intrusion detection/prevention systems
3. One-time use credit cards: Citibank MasterCard, DiscoverCard
4. Academic proposals: FC01, FC07, RIDE04, ESORICS08
5. Legal remedies, breach notification laws

## Consequences for consumers: identity fraud

1. “Full identity” costs only \$1-15
2. Time lost to resolve ID fraud
3. Denied financial services
4. Harassment by collection agencies
5. Criminal prosecution/arrest

## Variants 3 & 4

### 1. Variant 3: Database poisoning

- ▶ each relying party inserts fake user records in its database
- ▶ breach is detected when fake records are used
- ▶ card issuers may also use this technique

### 2. Variant 4: User-centric authorization

- ▶ notify/seek user approval for e.g. issuing new card, transferring user info across domains, high-value trans.
- ▶ deploy “physical presence” mechanisms for approval
